

PYTHON MODULES AND PACKAGES

AN INTRODUCTION

PYTHON MODULES AND PACKAGES

Modules and Packages facilitate modular programming.

Modular programming refers to the process of breaking a large, unwieldy programming task into separate, smaller, more manageable subtasks or modules.

PYTHON MODULES AND PACKAGES

What are advantages of modularizing code in a large application?

- Simplicity
- Maintainability
- Reusability
- Scoping

WRITING A MODULE

Three different styles of modules in Python

- **A module written in Python itself**
- **A module written in C and loaded dynamically at run-time**
- **A built-in module is intrinsically contained in the interpreter**

THE MODULE SEARCH PATH

Where can you `import` a module from?

- **The interpreter searches for the file**
 - In the current directory
 - In the PYTHONPATH environment variable list of directories
 - The directories configured as part of your Python installation

THE MODULE SEARCH PATH

Where should you put your module file?

- **To ensure you module is found place the file in:**
 - **The same directory as the input script or the current directory**
 - **Modify PYTHONPATH environment variable to contain the directory where it is located**
 - **Or in one of the directories already in the PYTHONPATH**
 - **In one of the directories configured as part of your Python installation**

THE MODULE SEARCH PATH

Where should you put your module file?

- **Or you can modify the `sys.path` list at run time**

```
sys.path.append(r'C:\Users\chris\ModulesDirectory')
```

12. Conclusion and Course Review

THE `import` STATEMENT

What forms can the import statement take?

- **The simplest form**

```
import <module_name>
```

- **The module contents are not *directly* accessible to the caller**
 - **A module creates a separate namespace**

THE `import` STATEMENT

What forms can the import statement take?

- **Individual objects from the module can be imported**

```
from <module_name> import <name(s)>
```

- **The individual objects are *directly* accessible to the caller**
 - **Objects are imported into the caller's symbol table**

THE `import` STATEMENT

What forms can the import statement take?

- **It is possible to import everything from a module at once**

```
from <module_names> import *
```

- **This places all the names of objects into the local symbol table**
 - **With the exception of any that begin with an underscore**
 - **NOTE: This isn't necessarily recommended**
 - **Unless you know all the names will not conflict and overwrite existing names**

THE `import` STATEMENT

What forms can the import statement take?

- **Individual objects can be imported with alternate names**

```
from <module_name> import <name> as <alt_name>
```

- **Making it possible to place names directly into the local symbol table**
 - **Avoiding conflicts with existing names**

THE `import` STATEMENT

What forms can the import statement take?

- **Import the entire module under an alternate name**

```
import <module_name> as <alt_name>
```

THE `import` STATEMENT

What forms can the import statement take?

- **Module contents can be imported from within a function definition**

TABLE OF CONTENTS

11. Subpackages
12. Conclusion and Course Review

THE `dir()` FUNCTION

View the defined names in a namespace

- The built-in function `dir()` returns a list of defined names in a namespace
- Without arguments, it produces an alphabetically sorted list of names in the current local symbol table

THE `dir()` FUNCTION

How to view the defined names in a namespace

- When given the name of a module as an argument, `dir()` lists the names defined in the module

TABLE OF CONTENTS

10. Importing `*` From a Package
11. Subpackages
12. Conclusion and Course Review

EXECUTING A MODULE AS A SCRIPT

Is a **module** also a Python **script**?

- Any `.py` file that contains a module is essentially also a Python script

EXECUTING A MODULE AS A SCRIPT

What if you don't want a module to generate output when imported?

- When a `.py` file is imported the dunder variable `__name__` is set to the name of the module
- When a `.py` file is run as a standalone script, `__name__` is set to the string `'__main__'`

TABLE OF CONTENTS

1. **Intro and Course Overview**
2. **Writing a Module**
3. **The Module Search Path**
4. **The `import` Statement**
5. **The `dir()` Function**
6. **Executing a Module as a Script**
-  7. **Reloading a Module**
8. Python Packages
9. Package Initialization
10. Importing `*` From a Package
11. Subpackages
12. Conclusion and Course Review

RELOADING A MODULE

A Module is only loaded once per interpreter session

- **This works fine for function and class definitions**
- **But modules can contain executable statements as well**
 - **Usually for initialization**
 - **These statements will only be executed the first time a module is imported**

RELOADING A MODULE

Is it possible to reload a module if needed?

- You can restart the interpreter
- Or use a function called `reload()` from the module `importlib`

TABLE OF CONTENTS

1. **Intro and Course Overview**
2. **Writing a Module**
3. **The Module Search Path**
4. **The `import` Statement**
5. **The `dir()` Function**
6. **Executing a Module as a Script**

9. Package Initialization
10. Importing `*` From a Package
11. Subpackages
12. Conclusion and Course Review

PYTHON PACKAGES

How to keep track of a growing number of modules

- **Packages allow for a hierarchical structuring of the module namespace using dot notation**
- **Example package structure:**

TABLE OF CONTENTS

1. **Intro and Course Overview**
2. **Writing a Module**
3. **The Module Search Path**
4. **The `import` Statement**
5. **The `dir()` Function**
6. **Executing a Module as a Script**
7. **Reloading a Module**
8. **Python Packages**
-  9. **Package Initialization**
10. Importing `*` From a Package
11. Subpackages
12. Conclusion and Course Review

PACKAGE INITIALIZATION

The `__init__.py` file

- If a file named `__init__.py` is present in a package directory, it is invoked when the package or a module in the package is imported

PACKAGE INITIALIZATION

The `__init__.py` file

- `__init__.py` can also be used to automatically import the modules from a package

TABLE OF CONTENTS

1. **Intro and Course Overview**
2. **Writing a Module**
3. **The Module Search Path**
4. **The `import` Statement**
5. **The `dir()` Function**
6. **Executing a Module as a Script**
7. **Reloading a Module**
8. **Python Packages**
9. **Package Initialization**
-  10. **Importing * From a Package**
11. Subpackages
12. Conclusion and Course Review

IMPORTING * FROM A PACKAGE

Expanding the current package

IMPORTING * FROM A PACKAGE

Add an `__init__.py` file with a list named `__all__`

pkg

`__init__.py`

`mod1.py`

`mod2.py`

`mod3.py`

`mod4.py`

IMPORTING * FROM A PACKAGE

The `__all__` list controls what is imported when `import *` is specified

- For a package, when `__all__` is not defined, `import *` does not import anything
- For a module, when `__all__` is not defined, `import *` imports everything (except names starting with an underscore)

TABLE OF CONTENTS

1. **Intro and Course Overview**
2. **Writing a Module**
3. **The Module Search Path**
4. **The `import` Statement**
5. **The `dir()` Function**
6. **Executing a Module as a Script**
7. **Reloading a Module**
8. **Python Packages**
9. **Package Initialization**
10. **Importing `*` From a Package**
-  11. **Subpackages**
12. Conclusion and Course Review

SUBPACKAGES

Packages can contain nested subpackages to arbitrary depth

SUBPACKAGES

It is possible to use a relative import

- `..` evaluates to the parent package
- `..sub_pkg` evaluates to the subpackage of the parent package

**CONGRATULATIONS
YOU'VE COMPLETED THE COURSE!**
